How perfect sampling? — Fills Algo

Relies on Acceptance Rejection Sampling

$P(\ C^T\ (z)\ |\ S^T\ (z\ —> x)\ )$ is computationally intractable.
But Acceptance Rejection decisions can be made.

For monotonic chains, this can be done by tracking extreme states.

Acceptance Rejection decisions can be made by simulating $\sqcap^{x \to z} \in \mathcal{U}^{x \to z}$ to ensure $S^T (x \longrightarrow z)$ occurs and tracking coupled parallel chains to detect if $C^T (z)$ occurs.
